Sangoma SBC Interoperability with Sipxcom High Availability
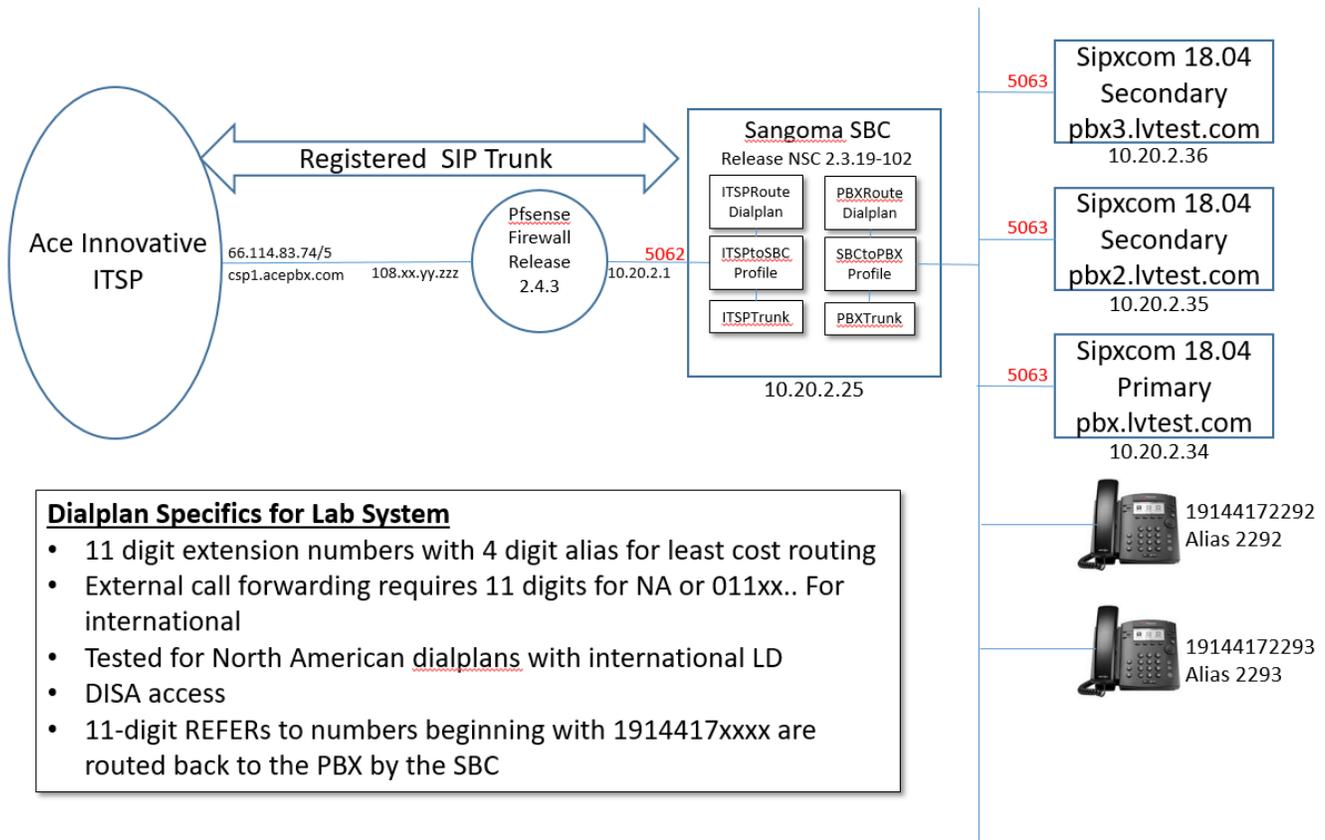

Introduction

This document provides an overview for configuring the Sangoma Session Border Controller (SBC) with the Sipxcom High Availability (HA) configuration. The following telephony features have been lab-tested with this configuration:

- Consultative and blind transfer of incoming and outgoing external calls from Polycom phones
- Call forwarding via the web portal
- DISA access - only works when the primary server is available
- Incoming and outgoing calls using a shared line with bridged line appearance (BLA) - only works when the primary server is available.

This document assumes working knowledge of Sipxcom HA, the Sangoma SBC, SIP, basic Freeswitch concepts, and regex expressions.

Step 1 - Plan Your SBC Configuration

Dialplan Specifics for Lab System
- 11 digit extension numbers with 4 digit alias for least cost routing
- External call forwarding requires 11 digits for NA or 011xx.. For international
- Tested for North American dialplans with international LD
- DISA access
- 11-digit REFERs to numbers beginning with 1914417xxxx are routed back to the PBX by the SBC

Per the above reference diagram, the Sangoma SBC sits behind Pfsense in a private network. Given that the Pfsense firewall protects the private network from malicious public Internet traffic, the SBC firewall was turned off. The Sangoma SBC has several high availability and clustering settings - those settings were not tested or validated with the Sipxcom HA configuration.

Sipxcom 18.04 and Sangoma NSC 2.3.19-102 releases were used in the lab testing. The Sipxcom HA cluster has 3 servers - one primary and two secondary servers; it also uses the **lvtest.com** SIP realm for failover. The Sipxcom default DNS settings were used during testing where phone registrations are spread evenly across all three servers in the HA cluster. The user extensions for the lab phones are 11-digit extensions (North American Dialplan) with 4 digit aliases that facilitates least-cost PSTN routing.For transfer testing, the Mongo Registrar was queried to ascertain successful call transfers through the SBC occurred to internal phones registered to different HA servers.

For incoming **external** calls that use DISA or calls that are transferred back out to the PSTN via a Polycom phone (e.g. cell phone), the SBC dialplan facing the Internet Telephony Service provider(ITSP) must distinguish between a call transfer going out to the PSTN versus a call being transferred to another user extension within Sipxcom (remember that the Sipxcom user extensions are 11 digits). When the SIP REFER is received as a result of a DISA call or call transfer, Sipxcom issues a REFER back out to the SBC. The SBC looks at the 11-digit number in the REFER-TO header - if the number begins with 1914417xxxx then the subsequent INVITE is sent back to the PBX.

In the SBC, the I**TSPtoSBC** SIP Profile is first defined for incoming external calls that assigns the 5062 port number that the profile will act upon. This profile is then linked to the **ITSPTrunk** SIP trunk which defines the far endpoint of the trunk, and optionally, whether the SIP trunk is registered along with registration credentials. Finally the **ITSPRoute** dialplan is defined and mapped to the profile that determines how the incoming call will be routed. There is the **SBCtoPBX** SIP profile, **SBCtoPBX** trunk, and **PBXRoute** dialplan with port 5063 that processes incoming calls from Sipxcom.

This wiki page provides good guidance on building dialplans using the Sangoma SBC https://wiki.sangoma.com/display/SBC/SIP+Refer+Handling. It is important to understand how the SBC processes REFERs. If an incoming external call arrives at the SBC, is routed to Sipxcom, and is then call-transferred, the REFER coming back from Sipxcom is processed by the **ITSPtoSBC** SIP profile and corresponding ITSPRoute dialplan, as that is where the original call is anchored. Likewise if a Sipxcom user placed an external call to the ITSP and the call is transferred, the incoming REFER to the SBC is processed by the **SBCtoPBX** Profile and **PBXRoute** dialplan as that is where the original call is anchored.

Step 2 - Set Port Forward and Outbound NAT on Pfsense

The Internet Telephony Service Provider used for Sipxcom HA and Sangoma SBC interoperability testing has its servers in the 66.114.83.0/24 class C sub-network range. For incoming traffic from the ITSP, Pfsense must be configured to allow all incoming traffic from this subnetwork destined for the public IP address of **108.xx.yy.zzz** with the port ranges of **5062-65535** to be forwarded to the SBC in the private network with the IP address of **10.20.2.25**. It should be noted that the Pfsense WAN interface supports multiple public IP addresses and by leveraging the Pfsense Virtual IP address feature, the **108.xx.yy.zzz** address has been reserved for SBC traffic.

For outbound traffic from the SBC to the ITSP, Pfsense must be programmed to NAT outgoing traffic from **10.20.2.25** to the public IP address reserved for SBC traffic - this is done via a mapping entry on the Psense **Firewall->NAT->Outbound** menu.

Firewall / NAT / Port Forward

| Port Forward | 1:1 | Outbound | NPt |

Rules

		Interface	Protocol	Source Address	Source Ports	Dest. Address	Dest. Ports	NAT IP	NAT Ports	Description	Actions
☐ ✔ ⤬		WAN	TCP/UDP	66.114.83.0/24	*	108.xx.yy.zzz	5062 - 65535	10.20.2.25	5062 - 65535	Sangoma SBC	✏️🗐 🗑️

Firewall / NAT / Outbound

| Port Forward | 1:1 | Outbound | NPt |

Outbound NAT Mode

| Mode | ☐ Automatic outbound NAT rule generation. (IPsec passthrough included) | ○ Hybrid Outbound NAT rule generation. (Automatic Outbound NAT + rules below) | ⦿ Manual Outbound NAT rule generation. (AON - Advanced Outbound NAT) | ○ Disable Outbound NAT rule generation. (No Outbound NAT rules) |

Mappings

		Interface	Source	Source Port	Destination	Destination Port	NAT Address	NAT Port	Static Port	Description	Actions
☐ ✔		WAN	10.20.2.25/32	*	*	*	108.xx.yy.zzz	*	✔	LAN to WAN	✏️🗐🗑️

Step 3 - Sipxcom Configuration to Support SBC

The key configuration changes to support the SBC are in the following areas:

- Creation of unmanaged gateway to the SBC
- Assign the unmanaged gateway to a dial plan
- Change NAT Traversal settings
- Changing BLA/SAA Firewall setting to test incoming external calls on BLA-enabled lines

Create an Unmanaged Gateway

Create an unmanaged gateway to the SBC at 10.20.2.25 using TCP transport and port 5063.

Assign the SBC Unmanaged Gateway to Dial Plan

Assign the SBC unmanaged gateway to the appropriate dial plans such as the **Long Distance** Dialplan.

	Name	Enabled	Address	Location	Model
☐	SBC	Enabled	10.20.2.25	All	Unmanaged gateway

NAT Traversal Settings

In the System -> Nat Traversal Settings menus, disable the **Enable NAT Traversal** and **Server Behind NAT** options. Also change **Address Type** to **Specify IP address** and provision the Public IP address with the IP address of the SipXcom primary voice server. Repeat this step for each of the secondary servers (10.20.2.35 and 10.20.2.36).

Change Firewall Settings for SAA/BLA

By default, the firewall settings to allow 5170 traffic from the phones to Sipxcom are disabled - this is used by bridge line appearance (BLA) lines on Sipxcom. Go to the **System->Firewall** menu and change the **SAA/BLA** TCP and UDP firewall settings from **CLUSTER** to **PUBLIC.** This change allows BLA to work on shared lines using Polycom phones in order to perform interoperability testing with the Sangoma SBC.

SAA/BLA TCP	10.20.2.34 : 5170	PUBLIC	☐
SAA/BLA UDP	10.20.2.34 : 5170	PUBLIC	☐

Step 4 - Configuring the Sangoma SBC

The Vmware version of the Sangoma SBC was used for this interoperability testing work and assumes the SBC has already been installed and operational. The changes to support Sipxcom HA include:

- Pointing the SBC DNS addresses at Sipxcom HA servers
- Creating G.711 media profiles for the ITSP
- Build the SIP Profiles
- Build the SIP Trunks
- Build the Call Routing Dialplans

Pointing the SBC DNS Addresses at Sipxcom HA Servers

Go to the **Configuration->IP Settings->Network** menu on the SBC and validate the IP Address assigned to the **Eth0** interface and **default gateway** from the installation. Point the SBC DNS addresses to the three Sipxcom HA servers.

Create G.711 Media Profile for the ITSP

The ITSP used for interoperability testing with the PSTN only supports G.711 codecs. Go into the **Configuration->Media->Media Profiles** menu of the SBC and create an ITSP profile that only supports PCMU and PCMA codecs.The **aceprofile** will be assigned to the ITSP and PBX SIP profiles of the SBC.

Build the SIP Profiles

From the planning diagram in step 1, there are two SIP Profiles required:

- **ITSPtoSBC** using Port **5062** - this SIP profile manages the traffic between the SBC and the ITSP
- **SBCtoPBX** using Port **5063** - this SIP profile manages the traffic between the SBC and Sipxcom

These two profiles are first created so that they can then be linked to the SIP trunks. The SIP profiles will then be updated after the corresponding Call Routing dialplans have been created.

Create the **ITSPtoSBC** profile using the default SBC profile settings except for the following fields:

- External SIP and RTP IP address fields are provisioned to **108.xx.yy.zzz** this is the public IP address assigned by Pfsense for the SBC. This is required as the SBC is sitting behind the firewall and not directly connected to the Internet. The SBC will replace the source IP address for outgoing SIP packets to the ITSP with the public **108.xx.yy.zzz** IP address assigned to the SBC.
- Port number is **5062** (see archiecture diagram in step 1 again)
- Transport is **UDP+TCP**
- Inbound and outbound media profiles are set to **aceprofile** (previous step) as the ITSP only supports G.711 codecs
- Validate that the Inbound **bypass Media option** is disabled - this means that all media goes through the SBC and simplifies troubleshooting.
- Enable the **Accept Blind Authentication** option

Create the **SBCtoPBX** profile using the default SBC profile settings except for the following fields:

- Port number is **5063** (see architecture diagram in step 1 again)
- Transport is **UDP+TCP**
- Inbound and outbound media profiles are set to **aceprofile** (previous step) as the ITSP only supports G.711 codecs
- Validate that the Inbound **bypass Media option** is disabled - this means that all media goes through the SBC and simplifies troubleshooting
- .Enable the **Accept Blind Authentication** option

⚠️ The IP Firewall service is stopped.

Profile - SBCtoPBX

Request SIP DNS Caching	Disable ⌄ ❓
Ignore 183 without SDP	Disable ⌄ ❓
Allow Privite Wire Info	Enable ⌄ ❓

Build the SIP Trunks

From the planning diagram in Step 1, there are two SIP trunks to be configured on the SBC:

- **ITSPTrunk -** points to the ITSP nodes defined at **csp1.acepbx.com**. The Ace Innovative ITSP actually presents two SRV records when queried by DNS - the primary server at **66.114.83.74** and the secondary server at **66.114.83.75**.
- **PBXTrunk** - points to the Sipxcom HA cluster with the SIP realm of **lvtest.com**. The Sangoma SBC is able to process DNS SRV records.

⚠ The IP Firewall service is stopped.

Trunk

🔍 [   ] [10 ⌄] Showing 1 to 2 of 2 entries

Name ⇕	Domain ⇕	SIP Profile ⇕
PBXTrunk	lvtest.com	SBCtoPBX
ITSPTrunk	csp1.acepbx.com	ITSPtoSBC

The SBC must be stopped prior to building the SIP Trunks and assigning the SIP Profile to the Trunk. The following configuration parameters are defined on the **ITSPTrunk** SIP Trunk:

- Domain name is the FQDN of the ITSP - in this case **csp1.acepbx.com**
- This is a registered SIP trunk, so User Name and Password credentials for the trunk are provided
- Map SIP Profile to the **ITSPtoSBC** profile
- Enable Registration on the SIP Trunk

Step 6 - Build the SBC Dialplans

Building the Call Routing Dialplans is an iterative process - for the lab system defined in step 1, two dialplans are defined:

- **ITSPRoute** - this dialplan will handle incoming calls from the ITSP to the SBC. Incoming INVITES and REFERs from the ITSP are processed by this call routing dialplan.
- **PBXRoute** - this dialplan will handle incoming calls from the PBX to the SBC. Incoming INVITES and REFERs from the PBX are processed by this call routing dialplan.

Go to the **Configuration->Call Routing** menu and build these two dialplans.

⚠ The IP Firewall service is stopped.

Basic Call Routing

Display Name ⇕	Description ⇕	Trace Call ⇕	Default Response ⇕
ITSPRoute	Dialplan for calls from ITSP	Enable	404
PBXRoute	Dialplan for calls from PBX	Enable	404
			Add

Advanced Call Routing

	No Advanced Call Routing
	Add

Once the call routing dialplans have been defined, they need to be mapped to the correct SIP profile as follows:

- In the **Configuration->Signaling->SIP Profile** menu, edit the **ITSPtoSBC** SIP profile, and in the Session Routing section, map the **ITSPRoute** dialplan to the profile, and save.
- Edit the SBCtoPBX SIP profile, and in the Session Routing section, map the **PBXRoute** dialplan to the profile, and save.

Once these configurations are applied to the SBC, the rules for each dialplan can be defined and tested.

Configuration / Signaling / SIP Profiles / SBCtoPBX

(Configuration UI screenshots showing QoS, NAT Traversal, Load Limits, Session Routing settings for ITSPtoSBC with Routing Plan "ITSPRoute" and SBCtoPBX with Routing Plan "PBXRoute")
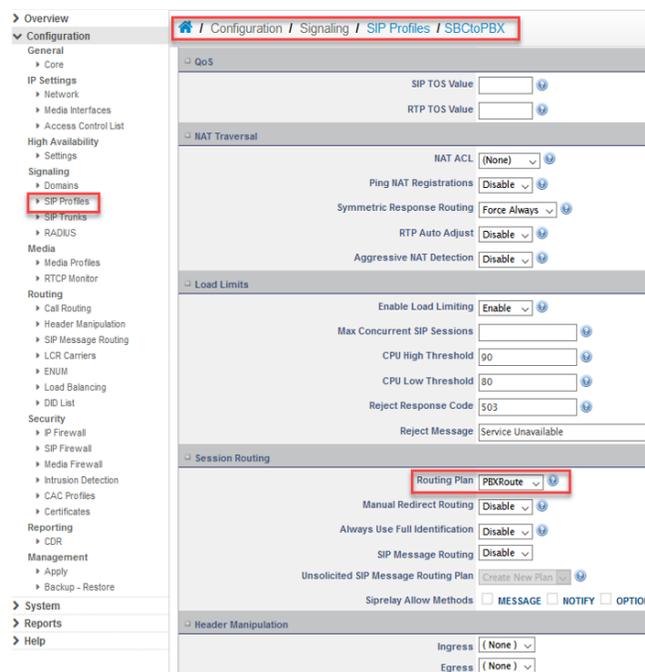

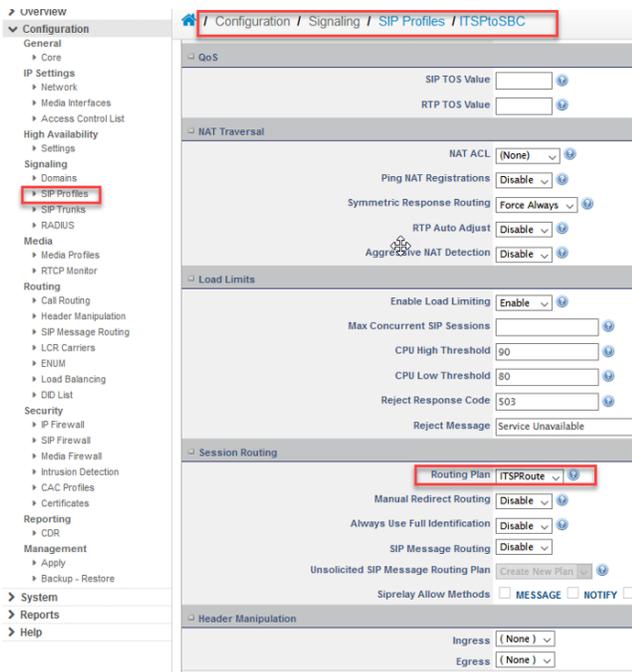

Before working through the details of the call routing dialplan rules, some simple call flow examples will provide clarity on the dialplan logic. Let's start with an incoming external call to 914-417-2292 (see architecture diagram in step 1), which is a Polycom phone behind Sipxcom. Because the call originated from the ITSP, the SBC processes the call using the **ITSPtoSBC** SIP Profile and corresponding **ITSPRoute** dialplan. The 19144172292 user answers the call and transfers the call to 2293 (which is an alias of 19144172293). To complete the transfer, Sipxcom issues a SIP REFER back to the SBC. Because the call being transferred originated from the ITSP, the **ITSPRoute** dialplan will process the REFER even though the REFER came from Sipxcom. The REFER from Sipxcom will have a **Refer-To:** header that begins with **sip:2293@lvtest.com;user=phone;** the SBC dialplan regex must parse this header, look at the **2293** destination address, and instruct the SBC to send an INVITE to **2293@lvtest.com** back to Sipxcom in order to complete the call transfer.

Let's use the same call flow but instead of transferring the call to 2293, the 19144172292 user transfers the call to the full 11-digit extension **19144172293**. The REFER from Sipxcom will have a **Refer-To:** header that begins with **sip:19144172293@lvtest.com;user=phone;** - the **ITSPRoute** dialplan must have a rule defined that sends the **SIP INVITE** for **19144172293** back to Sipxcom and not to the ITSP.

The Sipxcom **19144172292** user places an external call to the ITSP - because the call originated from Sipxcom,the **SBCtoPBX** SIP Profile and corresponding **PBXRoute** dialplan on the SBC processes the call. When the **19144172292** user transfers the call to **19144172293** or its **2293** alias, the **REFER** that is sent to the SBC is handled by the **SBCtoPBX** SIP profile and **PBXRoute** dialplan as the original outgoing call is anchored to this path. The **PBXRoute** dialplan must have dialplan rules that correctly routes calls for **1914417xxxx** and 4-digit aliases back to Sipxcom.

Final example - Sipxcom user **19144172292** has a call forwarding rule that forwards incoming calls to **16465551212** after 1 second**.** An external ITSP 9145551212 caller places a call to 19144172292. Sipxcom after 1 second sends an INVITE back to the SBC with a Request-line URI of **INVITE sip: 16465551212@10.20.2.25:5063** but the SIP TO: header has the original **sip:9144172292@lvtest.com** URI. Almost all SIP INVITES have Request-line URIs that are identical to the TO: header URI. However when call forwards are initiated by Sipxcom due to a call forwarding rule, the telephone numbers in the R-URI header and To: headers are different - the SBC must account for this when a call forwarding rule is applied to a Sipxcom user.

The Call Routing dialplan rules for both the **ITSPRoute** and **PBXRoute** dialplans are identical except for dialplan rule 9. In the following dialplan rule illustration, rule number 4 is a best practice and checks that SIP signaling comes from either the Sipxcom high availability servers or the ITSP - if not, processing stops with a SIP 405 error message and further dialplan processing terminates.

Dialplan rules 5 through 8 handle REFER processing - let's start with dialplan rule 5. In the dialplan assumptions documented in the architecture diagram in step 1, Sipxcom users are 11 digits and follow the North American telephone numbering plan. The numbering plan also assumes that **9144170000-9144179999** are assigned to Sipxcom users. If an external caller dialed 19144172292, the Sipxcom user answered the call, and then transferred the call to 19144172294, the REFER back to the SBC from Sipxcom would have **Refer-To** header of **19144172294@lvtest.com**. The regex in dialplan rule 5 checks whether the cialing number is 11 digits and begins with 1914417 - if it does, the regex populates the $1 variable with the called number and then sends the subsequent INVITE to Sipxcom.

Dialplan rules 6 and 7 go together and are a workaround to regex processing on the Sangoma SBC where some statements with multiple brackets fails to populate the $1 variable. In dialplan rule number 6, a check is made on whether the incoming packet is a SIP REFER packet - if so, the **REFER-TO** variable is populated with the contents of the **$1** variable containing the called telephone number. The regex in dialplan 7 checks whether the called number in the **Refer-To:** header is an 11 digit long-distance number or international call beginning with 011 - if so, then the subsequent INVITE is sent to the ITSP using the **REFER-TO** variable.

Dialplan plan rule 8 covers the case of a REFER containing any other called number - e.g. user **19144172292** transfers the call to alias **2294**. The regex in this dialplan takes the the called number populated in the **$1** variable and sends the INVITE to Sipxcom.

Note that dialplan processing stops for REFER dialplan rules 5, 7, and 8 if the matching condition was successful.

Further guidance on how to bridge REFERs with SIP Trunks is found here https://wiki.freepbx.org/display/SBC/SIP+Refer+Handling.This document provides useful regex examples for the Sangoma SBC https://wiki.freepbx.org/display/SBC/Regular+Expressions+in+the+Dial+Plan.

The final dialplan rule 9 forwards an incoming call from the ITSP to the Sipxcom PBX, and vice-versa. In the **ITSPRoute** dialplan rule (illustrated), the called number is custom bridged to the **PBXTrunk** which connects to Sipxcom. For an incoming call from Sipxcom to the ITSP, the **PBXRoute** dialplan would custom bridge the call to the **ITSPTrunk** in rule 9. Note that in the conditional query for the SIP INVITE packet, the request-line URI is queried and populated in the $1 variable by the underlying regex..

Rule	
Q [ ] 10 ⌄	**Showing 1 to 6 of 6 entries**

# ⌕	Description ⌕

Step 7 - Test Your SBC Configuration

Session Border controllers, and dialplan configurations (regex plans in particular) are detailed - a simple misspelling or an errant forward-slash in a trunk bridging operation can be problematic to trouble-shoot. In putting together this document, the following tests were performed to validate the configuration:

- Incoming ITSP call into Sipxcom - long-distance and international
- Outgoing external call - long-distance and international
- Incoming ITSP call into Sipxcom, answer call on one Polycom phone, and then test call transfer consultative and blind:
    - To another Polycom phone within Sipxcom using a 11-digit Sipxcom user number
    - To another Polycom phone within Sipxcom using a Sipxcom alias
    - To an external North American number from the Polycom phone
    - To an external international number from the Polycom phone
    - To an external North American number using the external phone connected through the ITSP
    - To an external international number using the external phone connected through the ITSP
- Outgoing Sipxcom to an ITSP, call is answered, and then test call transfer consultative and blind:
    - To another Polycom phone within Sipxcom using a 11-digit Sipxcom user number
    - To another Polycom phone within Sipxcom using a Sipxcom alias
    - To an external North American number from the Polycom Phone
    - To an external international number from the Polycom phone
    - To an external North American number using the external phone connected through the ITSP
    - To an external international number using the external phone connected through the ITSP
- Incoming internal and external calls into Sipxcom user, then call forward (from portal) to North American and International numbers
- Incoming internal and external calls into DISA, which then places call to internal, North America, and International numbers

- Incoming external calls into Sipxcom user enabled with bridged line appearance, answer call and check whether other BLA lines are flashing red, place call on hold, and pick up call on another phone.

The primary Sipxcom server in the high availability cluster was powered off, and the above tests were repeated. The tests using DISA (Authorization codes) and bridged line appearance failed as these features are only available when the primary server is operational - all other calls were successfully completed.
